

Braden Andersen: Stem cells really shouldn't be used for active cancer treatment. I think that's an important element to note. The reason is that stem cells are just so rich in growth factor that whatever tissue types you have in you, they're going to help grow. If you have an existing solid mass-type cancer within your body, that's not one of the better conditions to treat with stem. I personally think we should be a little bit careful with the application of stem into the eyes. It can be a little bit tricky. But otherwise, you'd be amazed how many different conditions stem can treat.
